HEAVY METAL POLLUTION IN GOMTI RIVER SEDIMENTS AROUND LUCKNOW, UTTAR PRADESH

S. KUMAR
Department of Geology, Lucknow University, Lucknow 226 007, India.

ABSTRACT

The clay fraction ($<2\ \mu m$) of Gomti river sediments shows relatively higher values for Cu, Mn, Pb, Cr and PO_4 in comparison to background values. Fe, Co and Ni do not show any increase and Cd is not within detectable limits. PO_4 shows very good positive correlation with Cu, Pb, Zn and Mn. It is concluded that municipal waste discharged into the river through drains is responsible for the higher values of heavy metals and PO_4, but in general Gomti river sediments can be termed as unpolluted with heavy metals.

INTRODUCTION

GOMTI is an alluvial plain river which originates from a swampy area in Pilibhit district and meets Ganga river in Ghazipur district, Uttar Pradesh. Two cities, Lucknow and Jaunpur, are situated on the banks of this river. Lucknow is a big city, with a population of more than 1.5 million and some industrial units. The entire Lucknow municipal waste, including industrial and sewage wastes, flows into the Gomti through small open drains or nalas. This waste alters the quality of the water, which in turn affects the associated sediments of the river. All fine-grained materials with large surface area are capable of accumulating heavy metal ions[1]. Thus the clay fraction (i.e. $<2\ \mu m$ fraction) in a fluvial system is most affected by heavy metal pollution and may acquire a level that may adversely affect the food chain of the aquatic ecosystem. Some of the heavy metals in sediments, specially Pb, Hg, Cu and Cd, are potentially hazardous not only to the aquatic ecosystem but also for human use. In the light of these facts the present paper deals with heavy metal concentration in Gomti river sediments around Lucknow.

The Gomti sediments[2] are made up of fine sand and mud fractions. The sand is litharenite to lithic graywacke in composition with characteristic heavy minerals indicating metamorphic provenance. Both plagioclases and alkali felspars are present in moderate amounts in sand and silt fractions. Clay fraction (i.e. $<2\ \mu m$) shows illite as the main mineral along with kaolinite, montmorillonite and meta-stable chlorite in minor amounts.

SAMPLING

A stretch of 9 km of Gomti river was selected for the present study (figure 1). Eight bank mud samples were collected in March 1987. The locations from where the samples were taken are shown in figure 1.

METHODOLOGY

The $<2\ \mu m$ fraction was separated from the mud in sedimentation cylinders using double-distilled water at 24°C. This fraction was then dried at 60°C in a porcelain dish. The dried sample (1 g) was digested in 10 ml of 65% pure conc. HNO_3 and

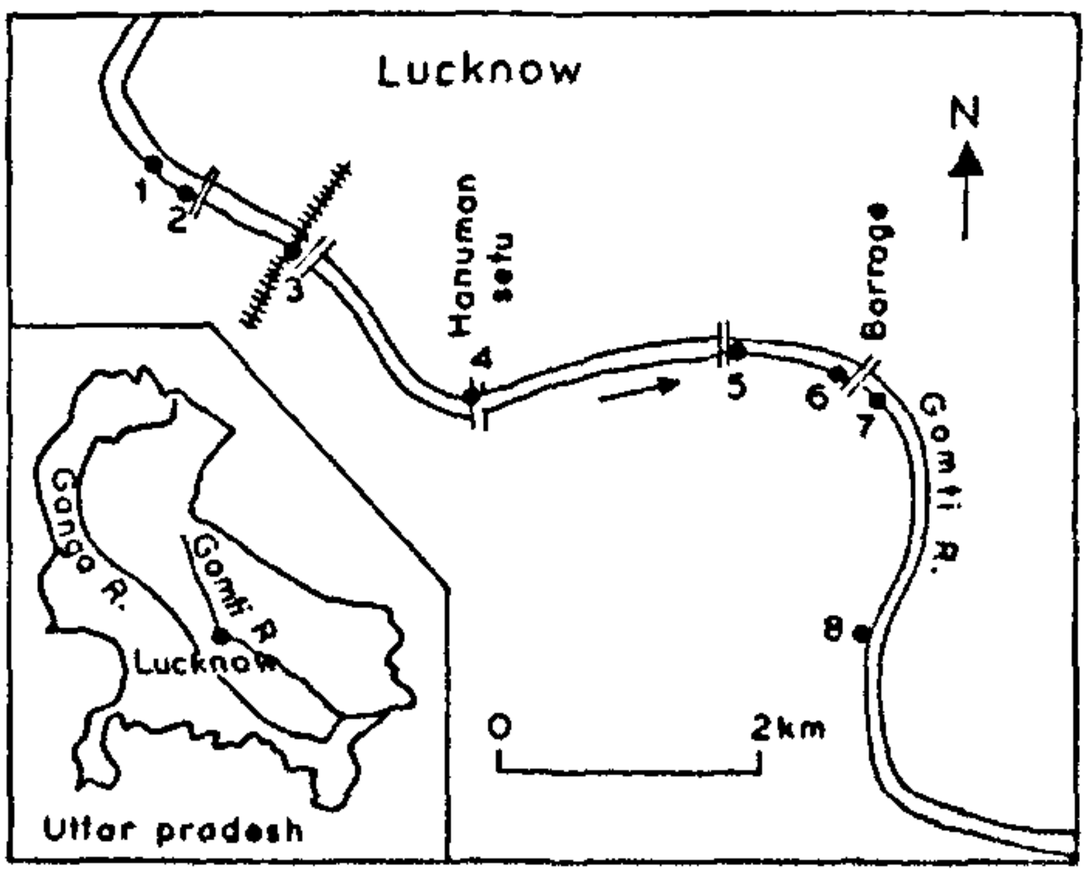

Figure 1. Location map of the samples of Gomti river sediments around Lucknow.

heated on a sand bath for 2 h at 140°C. After cooling it was made up to 50 ml and transferred to a plastic bottle. Suspended material was allowed to settle for 12 h. Heavy metals were determined using a Perkin Elmer atomic absorption spectrophotometer 3030. For determination of P, 10 ml of the solution was mixed with 3 ml $HCLO_4$ and heated for 5–6 h at 180°C. After cooling, 5 ml distilled water was added and the solution was made up to 50 ml. This solution (20 ml) was taken in a 50 ml flask and 10 ml HNO_3 + vanadium molybdate reagent was added, and the solution made up to 50 ml. After 10 min absorbance measurements were taken on an Elko II colorimeter with an S 42 E (418 nm) filter. The results are correct to ±6%.

RESULTS

The heavy metal content of the clay fraction of Gomti sediments is given in table 1. The values for sample no. 1 (locality no. 1) are taken as background values for the respective metals for the present study. From locality no. 1 to locality no. 8 (sample no. 8) downstream, there is a slight increase in Cu, Mn, Zn, Pb, Cr and PO_4 (figure 2). The PO_4 concentration at locality no. 1 is only 0.5% and as the municipal waste is dumped into the river from different drains, it increases and reaches the maximum (1.83%) near Hanuman Setu (locality no. 4). This increase in phosphate affects the quality of water as it causes rapid spread of flora, mostly algae, which results in depletion of oxygen content of the water. The highest concentrations of Mn, Zn and Pb were recorded near Bhaisa Kund (locality no. 6) and of Cr near locality no. 8. At present, no specific reason can be assigned for this increase.

Table 2 gives correlation coefficients for the data given in table 1. PO_4 shows a very good positive correlation with Cu, Pb, Zn and Mn, suggesting that these metals might be linked to PO_4. The source of PO_4 has yet to be established but most probably it is linked to the municipal waste. Cr shows a good correlation with Zn while Pb shows good correlation with Zn, Cu and Mn. As municipal waste is the only source of pollution for the Gomti the relative increase in heavy metals and PO_4 in the sediments can be ascribed to it. There is more or less no increase in Fe, Co and Ni. Cd is not within

detectable limits. In comparison with world shale standard[3] the Gomti clay fraction shows comparable values for Mn, Ni and Cr and low values for Cd and Fe. For Cu, Pb, Zn and Co the Gomti clay fraction has less than thrice the world standard shale values (table 1); however, in comparison with the background values (in the present case values for sample no. 1 are taken as the background values), these are less than double. Only one sample (sample no. 4) shows PO_4 values more than thrice the background value.

Thus there is a definite increase in heavy metals and PO_4 in Gomti river sediments due to anthropogenic activity but in comparison with background values and world shale standard[3] these sediments can be said to be unpolluted with heavy metals. A more than three-fold increase in PO_4, with which the heavy metals show good positive correlation, can be linked to organic pollution due to municipal waste discharged into the river. It is suggested that attempts should be made to minimize this by treating the municipal waste before it is dumped into Gomti river.

ACKNOWLEDGEMENTS

The author is grateful to Prof. S. K. Singh and Prof. G. Müller for encouragement and useful discussions. Thanks are also extended to Messrs M. Gästner, M. Rehrauer, L. Haamann and Frau Kuhn for help during the investigation. A fellowship to the author by the Alexander von Humboldt Foundation. W. Germany, to work in the Institut für Sedimentforschung, Heidelberg University, is gratefully acknowledged.

ANNOUNCEMENT

PEPTIDES AS NOVEL PHARMACEUTICALS

(12 and 13 July 1989, Royal Society of Medicine, London, UK)

This meeting will review the current knowledge of peptides in both physiology and pathophysiology and discusses the therapeutic implications for drugs affecting peptide synthesis or action. For details contact: Dr Renata Duke, IBC Technical Services Ltd, Bath House (3rd Floor), 56 Holborn Viaduct, London EC1A 2EX, UK.
